

ABSTRACT

[0029] A method of testing the hearing of a user utilizing a computer system. The computer system includes a computer and a speaker. The computer includes a first audio source and a second audio source. In addition, the computer can output an electrical signal to the speaker from the first audio source and from the second audio source. Further, the speaker can convert the electrical signal into a stimulus. The method includes: downloading a computer program from a server to the computer; executing the computer program on the computer, the execution of the computer program muting the first audio source; generating a stimulus; and receiving an input from the user that indicates that the user heard the stimulus.
